

KERNEL MASTERS

Why Linkers?

- Understanding linkers will help you build large programs.
- Understanding linkers will help you avoid dangerous programming errors.
- Understanding linking will help you understand how language scoping rules are implemented.
- Understanding linking will help you understand other important systems concepts.

Why Linkers?

Modularity

- Large program can be written as a collection of smaller files, rather than one monolithic mass.
- Can build libraries of common functions (more on this later) e.g., Math library, standard C library

Efficiency

- Time:
 - Change one source file, compile, and then re-link
 - No need to recompile other source files
- Space:
 - Libraries of common functions can be put in a single file...
 - Yet executable files and running memory images contain only code for the functions they actually use

What does a linker do?

Step 1: Symbol resolution

- Programs define and reference symbols (variables and functions)
- Symbol definitions are stored (by compilers) in a symbol table
 - Symbol table is an array of struct
 - Each entry includes name, type, size, and location of symbol
- Linker associates each symbol reference with exactly one symbol definition

What does a linker do?

Step 2: Relocation

- Merges separate code and data sections into single sections
- Relocates symbols from their relative locations in the .o files to their final absolute memory locations in the executable
- Updates all references to these symbols to reflect their new positions

Three kinds of object files

- Generated by compilers and assemblers
 - Relocatable object file
 - Contains code and data in a form that can be combined with other relocatable object files to form an executable
 - Each .o file is produced from exactly one source (.c) file
 - Shared object file
 - Special type of relocatable object file that can be loaded into memory and linked dynamically at either load or run time
 - Called Dynamic Link Libraries (DLLs) in Windows
- Generated by linkers
 - Executable object file
 - Contains code and data in a form that can be copied directly into memory and executed.

Executable and Linkable Format (ELF)

- Standard binary format for object files
- Derives from AT&T System V Unix (Common Object File Format COFF)
 - Later adopted by BSD Unix variants and Linux
- One unified format for
 - Executable object files
 - Relocatable object files (.o),
 - Shared object files (.so)
- Generic name: ELF binaries

ELF object file format

ELF header

Magic number, type (.o, exec, .so), machine, byte ordering, offset of section header

table, etc.

Segment header table

 Page size, virtual addresses memory segments (sections), segment sizes.

- .text section
 - Code
- .data section
 - Initialized (static) data
- .bss section
 - Uninitialized (static) data
 - Originally an IBM 704 assembly instruction;
 "Block Started by Symbol" ("Better Save Space")
 - Has section header but occupies no space

ELF header Segment header table (required for executables) . text section . data section .bss section .symtab .rel.txt .rel.data . debug Section header table (required for relocatables)

KERNEL MASTERS

0

ELF object file format

.symtab section

- Symbol table
- Procedure and static variable names
- Section names and locations

.rel.text section

- Relocation info for .text section
- Addresses of instructions that will need to be modified in the executable
- Instructions for modifying.

.rel.data section

- Relocation info for .data section
- Addresses of pointer data that will need to be modified in the merged executable

.debug section

Info for symbolic debugging (gcc -g)

Section header table

Offsets and sizes of each section

Linker Symbols

Every relocatable object module has a symbol table

Global symbols

- Symbols defined by a module that can be referenced by other modules
- E.g. non-static C functions and non-static global variables

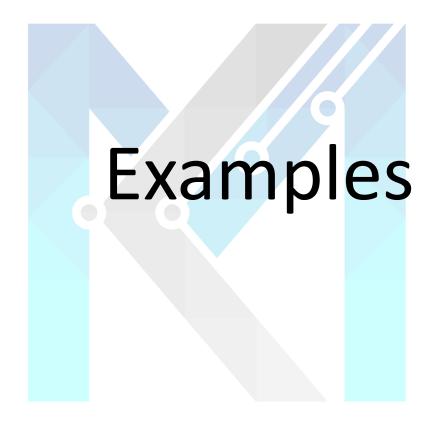

External symbols

 Global symbols that are referenced by a module but defined by some other module

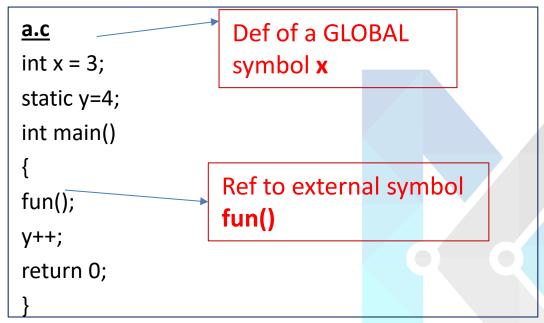

Local symbols

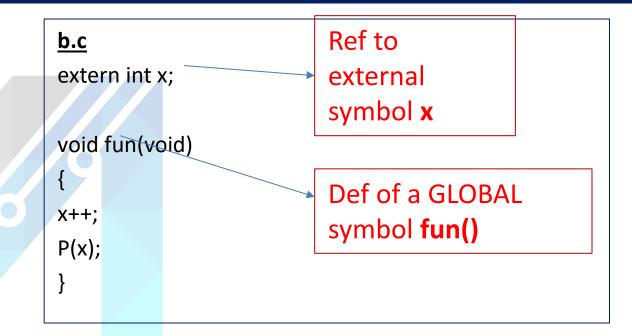

- Symbols that are defined and referenced exclusively by a module
- E.g. C functions and variables defined with the static attribute
- Local linker symbols are not local program variables (no symbols for local nonstatic program variables that are managed at runtime)

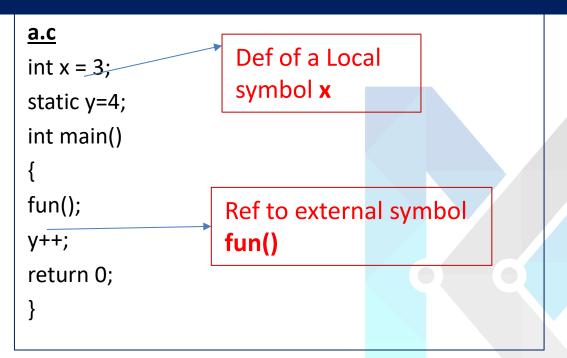

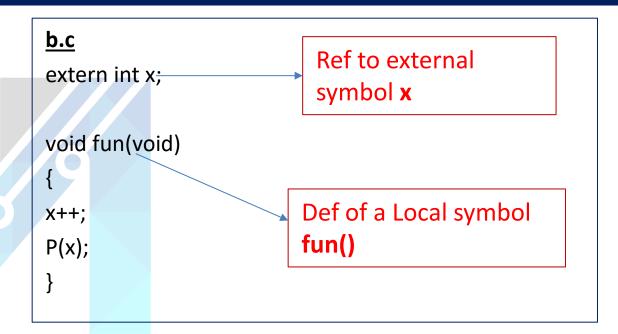

a.o symbol table

Symbol	.symtab entry?	Symbol Type	Module where defined	Section
Х	yes	GLOBAL	a.o	.data (D)
У	yes	LOCAL	a.o	.data (d)
fun	yes	EXTERN	b.o	.text (t)
main	yes	GLOBAL	a.o	.text (T)

b.o symbol table

Symbol	.symtab entry ?	Symbol Type	Module where defined	Section
х	yes	EXTERN	a.o	.data (d)
fun	yes	GLOBAL	b.o	.text (T)

Relocatable Object File

a.o main()
int x=3;
static int y=4;

fun()

b.o

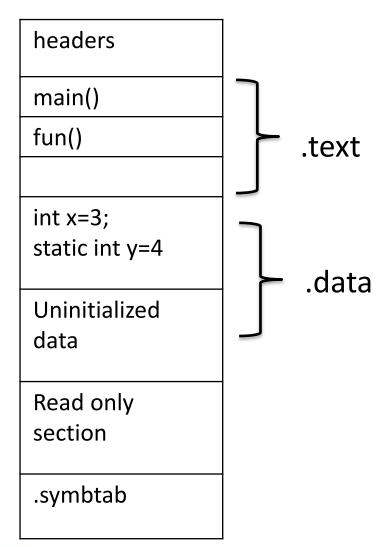

.text

.text

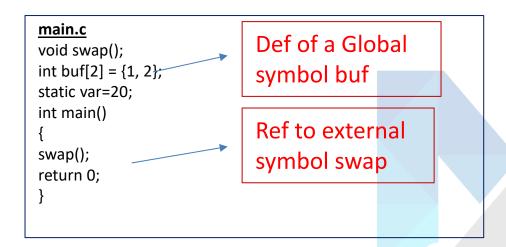

.data

.text .data

Executable Object File

```
swap.c
extern int buf[];
int *bufp0 = &buf[0];
int *bufp1;
void swap()
{
  int temp;
  bufp1 = &buf[1];
  temp = *bufp0;
  *bufp0 = *bufp1;
  *bufp1 = temp;
}
```

Ref to external symbol buf

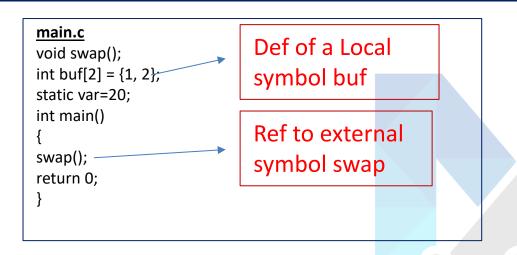

Def of a Local symbol bufp0, bufp1

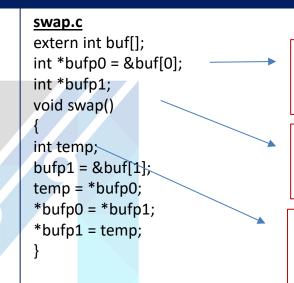

temp is a Local variable not a symbol.

main.o

Symbol	.symtab entry ?	Symbol Type	Module where defined	Section
buf	Yes	GLOBAL	main.o	.data
var	Yes	LOCAL	main.o	.data
main	Yes	GLOBAL	main.o	.text
swap	Yes	EXTERNAL	swap.o	.text

Ref to external symbol buf

Def of a Local symbol bufp0, bufp1

temp is a Local variable not a symbol.

swap.o

Symbol	.symtab entry?	Symbol Type	Module where defined	Section
buf	Yes	EXTERN	main.o	.data
bufp0	Yes	GLOBAL	swap.o	.data
bufp1	Yes	GLOBAL	swap.o	.bss
swap	Yes	GLOBAL	swap.o	.text
temp	no	temp A local variable; not a local symbol.		

GNU BinUtils

- ar: Creates static libraries, and inserts, deletes, lists, and extracts members.
- **strings:** Lists all of the printable strings contained in an object file.
- strip: Deletes symbol table information from an object file.
- nm: Lists the symbols defined in the symbol table of an object file.
- size: Lists the names and sizes of the sections in an object file.

GNU BinUtils

- **readelf:** Displays the complete structure of an object file, including all of the information encoded in the ELF header; subsumes the functionality of size and nm.
- **objdump:** The mother of all binary tools. Can display all of the information in an object file. Its most useful function is disassembling the binary instructions in the .text section.
- Idd: Lists the shared libraries that an executable needs at run time.
